Solo v13 — Local Multi-Agent Task & Handoff Orchestrator

Complete Implementation Specification

Status: Final Production Specification
Revision: v13 — Hermetic, Lock-Free, Production-Ready
Date: 2026-03-07
Implementation language: Go
Target implementer: AI coding agent
Prior revisions: v1–v12, incorporating five rounds of adversarial architectural review

---

How to Use This Document

This document is the **sole instruction manual** for building Solo. It contains every schema, every SQL boundary, every transition rule, every JSON contract, every error code, and every edge case mitigation required for a complete implementation.

If it's not in this document, don't build it. If this document is ambiguous on a point, choose the simpler interpretation and document the assumption with a code comment.

Read order for implementation:

1. §1–2: Understand what Solo is and how it works.
2. §3: Set up the database correctly.
3. §4: Create the full schema.
4. §5: Implement the status transition matrix.
5. §6: Build the core operations (exact SQL provided).
6. §7: Build the worktree manager.
7. §8: Build context bundles.
8. §9: Build every CLI command with the exact JSON contracts.
9. §10: Implement the error taxonomy.

10. §11: Verify against the invariant checklist.
11. §12–13: Configuration and development phases.

---

1. Project Overview

Solo is a local CLI-based task tracking and orchestration system for coordinating multiple coding agents on a single developer machine.

Problem: When a developer uses multiple AI coding agents (Claude Code, Aider, Codex CLI, Cursor), those agents forget context between sessions, duplicate each other's work, and produce broken handoffs. No durable coordination layer exists between them.

Solution: Solo is a local SQLite-backed ledger that tracks tasks, active work sessions, agent handoffs, and workspace state. It provides a deterministic CLI that agents can call to coordinate without conflicting.

1.1 Design Constraints

- **Single machine.** All state lives on one device. No network required.
- **No background processes.** No daemon, no supervisor. Recovery is lazy and triggered by CLI usage.
- **CLI-only.** All interaction is via the `solo` binary. All structured output is JSON.
- **Agent-agnostic.** Solo doesn't know or care which LLM powers the agent.
- **Work preservation.** Solo never destroys work product (worktrees, branches, commits) without explicit `--force`.

---

2. Architecture

Process model: Every `solo` invocation is a short-lived process. It opens the SQLite database, performs its operation within a transaction, and exits. There is no long-running server.

Concurrency model: Multiple `solo` processes may run simultaneously. SQLite WAL mode with `busy_timeout` handles concurrent access. Optimistic Concurrency Control (OCC) `version` fields prevent lost updates. Atomic conditional SQL prevents double-reservations.

Lazy recovery: On every CLI invocation, Solo performs a non-blocking fast zombie scan to

detect crashed sessions via PID checking.

---

3. Database

3.1 Location

```
<repo-root>/.solo/solo.db
```

File Discovery Rule: Solo discovers the repo root by walking up from CWD until it finds a `.git` entry (file or directory). Use `os.Stat` — not `exec.Command("git", ...)` — so it works correctly when the CLI is invoked from inside a worktree.

3.2 Connection Setup

Apply these PRAGMAs on **every** database connection, before any operation:

```
PRAGMA journal_mode = WAL;
PRAGMA foreign_keys = ON;
PRAGMA busy_timeout = 5000;
PRAGMA synchronous = NORMAL;
PRAGMA cache_size = -64000;   -- 64MB page cache
```

The zombie scan overrides `busy_timeout = 0` before its write attempt (see §6.3).

---

4. Schema

4.1 Tasks

```
CREATE TABLE tasks (
    id                  TEXT PRIMARY KEY,
    title               TEXT NOT NULL CHECK (length(trim(title)) > 0),
    description         TEXT DEFAULT '',
    type                TEXT NOT NULL DEFAULT 'task'
                        CHECK (type IN ('task', 'bug', 'feature', 'chore', 'spike
    status              TEXT NOT NULL DEFAULT 'open'
                        CHECK (status IN (
                            'open', 'triaged', 'ready', 'in_progress',
                            'in_review', 'blocked', 'done', 'cancelled'
                        )),
```

```
    priority            INTEGER NOT NULL DEFAULT 3
                        CHECK (priority BETWEEN 1 AND 5),
    acceptance_criteria TEXT DEFAULT '',
    definition_of_done  TEXT DEFAULT '',
    affected_files      TEXT DEFAULT '[]',  -- JSON array of file paths
    labels              TEXT DEFAULT '[]',  -- JSON array of strings
    parent_task         TEXT REFERENCES tasks(id) ON DELETE SET NULL,

    version             INTEGER NOT NULL DEFAULT 1,  -- OCC version counter
    created_at          TEXT NOT NULL DEFAULT (strftime('%Y-%m-%dT%H:%M:%fZ', 'no
    updated_at          TEXT NOT NULL DEFAULT (strftime('%Y-%m-%dT%H:%M:%fZ', 'no
);

CREATE INDEX idx_tasks_status ON tasks(status);
CREATE INDEX idx_tasks_priority ON tasks(priority);
CREATE INDEX idx_tasks_parent ON tasks(parent_task);

-- Auto-update updated_at on every mutation
CREATE TRIGGER tasks_updated_at
AFTER UPDATE ON tasks
FOR EACH ROW BEGIN
    UPDATE tasks SET updated_at = strftime('%Y-%m-%dT%H:%M:%fZ', 'now')
    WHERE id = NEW.id;
END;
```

4.2 Task Dependencies

```
CREATE TABLE task_dependencies (
    task_id     TEXT NOT NULL REFERENCES tasks(id) ON DELETE CASCADE,
    depends_on  TEXT NOT NULL REFERENCES tasks(id) ON DELETE RESTRICT,
    PRIMARY KEY (task_id, depends_on),
    CHECK (task_id != depends_on)    -- No self-dependencies
);

CREATE INDEX idx_deps_task ON task_dependencies(task_id);
CREATE INDEX idx_deps_depends_on ON task_dependencies(depends_on);
```

Circular dependency check: Before inserting, run a recursive CTE to confirm no cycle would be introduced. Reject with `CIRCULAR_DEPENDENCY` if one is detected.

4.3 Reservations

```
CREATE TABLE reservations (
    id              TEXT PRIMARY KEY,               -- UUID v4
```

```
    task_id         TEXT NOT NULL REFERENCES tasks(id) ON DELETE RESTRICT,
    worker_id       TEXT NOT NULL CHECK (length(trim(worker_id)) > 0),
    active          INTEGER NOT NULL DEFAULT 1,     -- 1 = active, 0 = ended

    reserved_at     TEXT NOT NULL DEFAULT (strftime('%Y-%m-%dT%H:%M:%fZ', 'now'))
    expires_at      TEXT NOT NULL,                  -- reserved_at + ttl_sec
    ttl_sec         INTEGER NOT NULL DEFAULT 3600,  -- 1 hour default

    released_at     TEXT,
    release_reason  TEXT CHECK (release_reason IN (
                        'completed', 'expired', 'handoff', 'manual', 'recovered',
                    )),
    worktree_path   TEXT,
    machine_id      TEXT NOT NULL DEFAULT 'default'
);

-- CRITICAL: prevents double-reservation at the database level.
-- Two concurrent INSERT attempts for the same task_id where active=1
-- will cause one to fail with a UNIQUE constraint violation.
CREATE UNIQUE INDEX idx_reservations_active_task
ON reservations(task_id) WHERE active = 1;

CREATE INDEX idx_reservations_expires ON reservations(expires_at) WHERE active =
```

4.4 Sessions

```
CREATE TABLE sessions (
    id              TEXT PRIMARY KEY,               -- UUID v4
    task_id         TEXT NOT NULL REFERENCES tasks(id) ON DELETE RESTRICT,
    reservation_id  TEXT NOT NULL REFERENCES reservations(id) ON DELETE RESTRICT,
    worker_id       TEXT NOT NULL,

);

CREATE INDEX idx_handoffs_task ON handoffs(task_id);
CREATE INDEX idx_handoffs_status ON handoffs(status) WHERE status = 'pending';
```

4.6 Worktrees

```
CREATE TABLE worktrees (
    path            TEXT PRIMARY KEY,
```

```
    task_id         TEXT NOT NULL REFERENCES tasks(id) ON DELETE RESTRICT,
    branch_name     TEXT NOT NULL,
    base_ref        TEXT NOT NULL DEFAULT 'origin/main',
    base_commit_sha TEXT,

    status          TEXT NOT NULL DEFAULT 'active'
                    CHECK (status IN ('active', 'cleanup_pending', 'cleaned')),
    disk_usage_bytes INTEGER,
    created_at      TEXT NOT NULL DEFAULT (strftime('%Y-%m-%dT%H:%M:%fZ', 'now'))
    cleaned_at      TEXT
);

CREATE INDEX idx_worktrees_task ON worktrees(task_id);
CREATE INDEX idx_worktrees_status ON worktrees(status);
```

4.7 Recovery Records

```
CREATE TABLE recovery_records (
    id                  INTEGER PRIMARY KEY AUTOINCREMENT,
    task_id             TEXT NOT NULL REFERENCES tasks(id),
    session_id          TEXT REFERENCES sessions(id),
    reason              TEXT NOT NULL CHECK (reason IN (
                            'crash_detected', 'reservation_expired', 'manual_reco
                            'session_timeout', 'worktree_conflict'
                        )),
    previous_status     TEXT NOT NULL,
    recovered_to        TEXT NOT NULL DEFAULT 'ready',
    worktree_state      TEXT CHECK (worktree_state IN (
                            'clean', 'dirty', 'conflicts', 'missing', NULL
                        )),
    uncommitted_files   TEXT DEFAULT '[]',          -- JSON array of file paths
    diagnostic_json     TEXT,
    created_at          TEXT NOT NULL DEFAULT (strftime('%Y-%m-%dT%H:%M:%fZ', 'no
);
```

4.8 Audit Events

```
CREATE TABLE audit_events (
    id              INTEGER PRIMARY KEY AUTOINCREMENT,
    task_id         TEXT REFERENCES tasks(id) ON DELETE CASCADE,
    event_type      TEXT NOT NULL,
    actor_type      TEXT NOT NULL CHECK (actor_type IN ('human', 'agent', 'system
    actor_id        TEXT NOT NULL,
    old_value_json  TEXT,
```

```
    new_value_json  TEXT,
    created_at      TEXT NOT NULL DEFAULT (strftime('%Y-%m-%dT%H:%M:%fZ', 'now'))
);

CREATE INDEX idx_audit_task ON audit_events(task_id, created_at);
```

4.9 FTS5 Search Index

```
CREATE VIRTUAL TABLE tasks_fts USING fts5(
    id, title, description, acceptance_criteria,
    content='tasks', content_rowid='rowid'
);

CREATE TRIGGER tasks_fts_ai AFTER INSERT ON tasks BEGIN
    INSERT INTO tasks_fts(rowid, id, title, description, acceptance_criteria)
    VALUES (new.rowid, new.id, new.title, new.description, new.acceptance_criteri
END;

CREATE TRIGGER tasks_fts_au AFTER UPDATE ON tasks BEGIN
    INSERT INTO tasks_fts(tasks_fts, rowid, id, title, description, acceptance_cr
    VALUES ('delete', old.rowid, old.id, old.title, old.description, old.acceptan
    INSERT INTO tasks_fts(rowid, id, title, description, acceptance_criteria)
    VALUES (new.rowid, new.id, new.title, new.description, new.acceptance_criteri
END;

CREATE TRIGGER tasks_fts_ad AFTER DELETE ON tasks BEGIN
    INSERT INTO tasks_fts(tasks_fts, rowid, id, title, description, acceptance_cr
    VALUES ('delete', old.rowid, old.id, old.title, old.description, old.acceptan
END;
```

4.10 Schema Version and Config

```
CREATE TABLE schema_version (
    version     INTEGER PRIMARY KEY,
    applied_at  TEXT NOT NULL DEFAULT (strftime('%Y-%m-%dT%H:%M:%fZ', 'now')),
    description TEXT
);

INSERT INTO schema_version (version, description) VALUES (1, 'Solo v13 initial sc

CREATE TABLE config (
    key     TEXT PRIMARY KEY,
    value   TEXT NOT NULL
);
```

```
-- Defaults inserted by solo init:
-- 'machine_id'        → hostname or user-provided value
-- 'default_ttl_sec'   → '3600'
-- 'max_ttl_sec'       → '86400'
-- 'max_worktrees'     → '5'
-- 'base_ref'          → 'origin/main'
-- 'worktree_dir'      → '.solo/worktrees'
-- 'session_ttl_sec'   → '14400'
-- 'max_tokens'        → '8000'
```

---

5. Status Transition Matrix

5.1 Valid Transitions

```
open         → triaged, ready, cancelled
triaged      → ready, blocked, cancelled
ready        → in_progress, blocked, cancelled
in_progress  → in_review, blocked, ready, cancelled
in_review    → done, in_progress, blocked, cancelled
blocked      → ready, triaged, cancelled
done         → (terminal — no transitions out)
cancelled    → open  (reopen only)
```

Implementation: Store as `map[string][]string` in Go. Every call to `solo task update` must validate the transition. Reject invalid transitions with `INVALID_TRANSITION`.

5.2 Automatic Transitions

These transitions happen as side effects of other commands. They do **not** require explicit `solo task update`:

Trigger	Transition	Notes
`solo session start T-142`	`ready → in_progress`	Task must be `ready`
`solo session end --result completed`	`in_progress → in_review`	Default; override with `--status done`
`solo session end --result failed`	No transition	Stays `in_progress`; human or agent decides next step

`solo session end --result handoff`	`in_progress → ready`	Released for next worker
`solo session end --result abandoned`	`in_progress → ready`	Released for next worker
`solo session end --result interrupted`	`in_progress → ready`	Released for next worker
`solo handoff create T-142`	`in_progress → ready`	Atomic with session end and reservation release
`solo task recover T-142`	`in_progress → ready` or `blocked → ready`	Clears reservation and session
Reservation expiry (zombie scan)	`in_progress → ready`	Detected lazily on next CLI invocation

5.3 The Strict Lock Rule (CRITICAL)

If a task has an **active reservation** (`SELECT 1 FROM reservations WHERE task_id = ? AND active = 1`), any call to `solo task update` for that task **must be rejected** with error `TASK_LOCKED`.

State mutations on actively reserved tasks are only permitted through:

- `solo session end`
- `solo handoff create`
- `solo task recover`

This prevents race conditions where an external process changes a task's status while an agent is actively working on it.

5.4 Transition Validation Error Format

```
{
  "error": {
    "code": "INVALID_TRANSITION",
    "message": "Cannot transition from 'open' to 'done'. Valid transitions from '
    "current_status": "open",
    "requested_status": "done",
    "valid_transitions": ["triaged", "ready", "cancelled"],
```

```
    "retryable": false
  }
}
```

---

6. Core Operations: Exact SQL and Behavior

6.1 Task ID Generation

Inside a `BEGIN IMMEDIATE` transaction:

```
INSERT INTO tasks (id, title, description, type, priority, acceptance_criteria,
    definition_of_done, affected_files, labels, parent_task)
VALUES (
    'T-' || (COALESCE(
        (SELECT MAX(CAST(SUBSTR(id, 3) AS INTEGER)) FROM tasks), 0
    ) + 1),
    ?, ?, ?, ?, ?, ?, ?, ?, ?
);
```

Because this runs inside `BEGIN IMMEDIATE`, no two concurrent processes can generate the same ID.

6.2 Atomic Reservation (Session Start)

This is the most critical operation. It must be a single `BEGIN IMMEDIATE` transaction:

```
BEGIN IMMEDIATE;

-- Step 1: Verify task exists and is in 'ready' status
SELECT id, version FROM tasks WHERE id = ? AND status = 'ready';
-- If not found: rollback, return TASK_NOT_FOUND or TASK_NOT_READY

-- Step 2: Insert reservation (unique index prevents double-reservation)
INSERT INTO reservations (id, task_id, worker_id, expires_at, ttl_sec, machine_id
VALUES (
    ?,   -- new UUID
    ?,   -- task_id
    ?,   -- worker_id
    datetime('now', '+' || ? || ' seconds'),  -- expires_at
    ?,   -- ttl_sec
    ?    -- machine_id
);
-- If UNIQUE constraint fails on idx_reservations_active_task:
```

```
-- rollback, return TASK_LOCKED

-- Step 3: Create session record
INSERT INTO sessions (id, task_id, reservation_id, worker_id, agent_pid)
VALUES (?, ?, ?, ?, ?);

-- Step 4: Transition task status
UPDATE tasks
SET status = 'in_progress', version = version + 1, updated_at = strftime('%Y-%m-%
WHERE id = ? AND version = ?;
-- If 0 rows updated: rollback, return VERSION_CONFLICT

-- Step 5: Write audit event
INSERT INTO audit_events (task_id, event_type, actor_type, actor_id, old_value_js
VALUES (?, 'session.start', 'agent', ?, ?, ?);

COMMIT;
```

After the transaction commits: create the git worktree (§7.1). If worktree creation fails, run a compensating transaction to undo steps 2–5.

6.3 Lazy Zombie Scan

Called at the start of **every** CLI invocation. Must be non-blocking.

```
func LazyZombieScan(db *sql.DB) {
    // Use busy_timeout = 0 to prevent CLI latency storms.
    // If the DB is locked, another CLI is running — skip scan and proceed.
    _, err := db.Exec("PRAGMA busy_timeout = 0")
    if err != nil {
        return
    }

    _, err = db.Exec("BEGIN IMMEDIATE")
    if err != nil {
        // SQLITE_BUSY: another writer is active. Skip scan.
        db.Exec("PRAGMA busy_timeout = 5000") // restore for main operation
        return
    }

    // Find all sessions with no ended_at and a recorded PID
    rows, _ := db.Query(`
        SELECT s.id, s.task_id, s.reservation_id, s.agent_pid, r.id as res_id
        FROM sessions s
        JOIN reservations r ON r.id = s.reservation_id
        WHERE s.ended_at IS NULL AND s.agent_pid IS NOT NULL
```

```
    `)

    var toRecover []zombieSession
    for rows.Next() {
        var z zombieSession
        rows.Scan(&z.SessionID, &z.TaskID, &z.ReservationID, &z.PID, &z.ResID)
        if isProcessDead(z.PID) {
            toRecover = append(toRecover, z)
        }
    }
    rows.Close()

    for _, z := range toRecover {
        recoverZombieSession(db, z) // within the open transaction
    }

    // Also expire reservations past expires_at
    db.Exec(`
        UPDATE reservations SET active = 0, released_at = strftime('%Y-%m-%dT%H:%
            release_reason = 'expired'
        WHERE active = 1 AND expires_at < strftime('%Y-%m-%dT%H:%M:%fZ', 'now')
    `)

    db.Exec("COMMIT")

    // Restore busy_timeout for the main CLI operation
    db.Exec("PRAGMA busy_timeout = 5000")
}

// isProcessDead returns true if the PID does not exist on the OS.
func isProcessDead(pid int) bool {
    if pid <= 0 {
        return false
    }
    process, err := os.FindProcess(pid)
    if err != nil {
        return true
    }
    err = process.Signal(syscall.Signal(0))
    return errors.Is(err, os.ErrProcessDone) || errors.Is(err, syscall.ESRCH)
}
```

6.4 Atomic Handoff

```
BEGIN IMMEDIATE;
```

```
-- End the session
UPDATE sessions
SET ended_at = strftime('%Y-%m-%dT%H:%M:%fZ', 'now'), result = 'handoff'
WHERE id = ? AND ended_at IS NULL;

-- Release the reservation
UPDATE reservations
SET active = 0, released_at = strftime('%Y-%m-%dT%H:%M:%fZ', 'now'), release_reas
WHERE id = ? AND active = 1;

-- Create handoff record
INSERT INTO handoffs (id, task_id, session_id, reservation_id, from_worker, to_wo
    summary, remaining_work, files_touched, commits_json, worktree_status)
VALUES (?, ?, ?, ?, ?, ?, ?, ?, ?, ?, ?);

-- Transition task back to ready
UPDATE tasks
SET status = 'ready', version = version + 1, updated_at = strftime('%Y-%m-%dT%H:%
WHERE id = ? AND version = ?;
-- If 0 rows: rollback, return VERSION_CONFLICT

-- Audit event
INSERT INTO audit_events (task_id, event_type, actor_type, actor_id, old_value_js
VALUES (?, 'handoff.created', 'agent', ?, ?, ?);

COMMIT;
```

6.5 Session End

```
BEGIN IMMEDIATE;

UPDATE sessions
SET ended_at = strftime('%Y-%m-%dT%H:%M:%fZ', 'now'),
    result = ?,        -- 'completed', 'failed', 'interrupted', 'abandoned'
    notes = ?,
    commits = ?,
    files_changed = ?
WHERE id = ? AND ended_at IS NULL;

UPDATE reservations
SET active = 0,
    released_at = strftime('%Y-%m-%dT%H:%M:%fZ', 'now'),
    release_reason = ?  -- maps from result
WHERE id = ? AND active = 1;

-- Automatic status transition per §5.2
```

```
UPDATE tasks
SET status = ?,        -- see §5.2 table
    version = version + 1,
    updated_at = strftime('%Y-%m-%dT%H:%M:%fZ', 'now')
WHERE id = ? AND version = ?;

INSERT INTO audit_events (task_id, event_type, actor_type, actor_id, old_value_js
VALUES (?, 'session.end', 'agent', ?, ?, ?);

COMMIT;
```

6.6 Task Recovery

Full recovery procedure for `solo task recover <task-id>`:

```
BEGIN IMMEDIATE;

-- 1. Find open session (if any)
SELECT id, reservation_id, agent_pid, worktree_path
FROM sessions WHERE task_id = ? AND ended_at IS NULL;

-- 2. End the session
UPDATE sessions
SET ended_at = strftime('%Y-%m-%dT%H:%M:%fZ', 'now'), result = 'interrupted'
WHERE task_id = ? AND ended_at IS NULL;

-- 3. Release the reservation
UPDATE reservations
SET active = 0, released_at = strftime('%Y-%m-%dT%H:%M:%fZ', 'now'), release_reas
WHERE task_id = ? AND active = 1;

-- 4. Reset task status (with OCC check)
UPDATE tasks
SET status = 'ready', version = version + 1, updated_at = strftime('%Y-%m-%dT%H:%
WHERE id = ? AND version = ?;
-- If 0 rows: VERSION_CONFLICT

-- 5. Create recovery record
INSERT INTO recovery_records (task_id, session_id, reason, previous_status, recov
    worktree_state, uncommitted_files, diagnostic_json)
VALUES (?, ?, 'manual_recovery', ?, 'ready', ?, ?, ?);

INSERT INTO audit_events (task_id, event_type, actor_type, actor_id, old_value_js
VALUES (?, 'task.recovered', 'system', 'cli', ?, ?);

COMMIT;
```

Note: `solo task recover` requires `--version N`. This is the OCC version of the task. Without it, two concurrent recovery attempts could both succeed and leave the task in an inconsistent state.

---

7. Worktree Lifecycle

7.1 Allocation (`solo session start`)

Called **after** the database transaction commits. If this fails, run the compensating DB rollback.

```
1. Empty repo check (CRITICAL):
   Run: git rev-parse HEAD
   If fails (exit code non-zero): return REPO_EMPTY, rollback reservation.

2. Determine branch name:
   Format: solo/{machine_id}/{task_id}
   Example: solo/laptop-john/T-142

3. Determine worktree path:
   {worktree_dir}/{task_id}
   Example: .solo/worktrees/T-142

4. Run: git worktree add <path> -b <branch> <base_ref>
   If fails with "index.lock exists": retry up to 3 times with 100ms backoff.
   If fatally fails after retries: rollback reservation, return WORKTREE_ERROR.

5. Insert into worktrees table:
   (path, task_id, branch_name, base_ref, base_commit_sha, status='active')

6. Update session record with worktree_path and branch.

7. Update reservation record with worktree_path.
```

7.2 Cleanup (`solo worktree cleanup`)

```
For each worktree where status != 'cleaned':
  1. Skip if there is an active reservation or session for task_id.
  2. Run: git status --porcelain <path>
     If dirty (non-empty output):
       - If NOT --force: print warning, skip this worktree.
       - If --force: proceed to deletion.
```

```
3. Run: git worktree remove <path>
   If --force: git worktree remove --force <path>
4. Branch deletion:
   - Without --force: git branch -d <branch>  (safe delete; ignore errors if no
   - With --force:    git branch -D <branch>  (force delete; permanently destro
5. Update DB: worktrees SET status='cleaned', cleaned_at=NOW()
```

7.3 Max Worktrees Enforcement

Before creating a new worktree in §7.1:

```
SELECT COUNT(*) FROM worktrees WHERE status = 'active';
```

If count >= `max_worktrees` config value (default 5): return `WORKTREE_LIMIT_EXCEEDED`.

7.4 Git Error Classification

Error	Code	Retryable
Repo has no commits	`REPO_EMPTY`	No
`.git/index.lock` exists	`GIT_INDEX_LOCKED`	Yes (auto-retry 3×)
Path already exists as worktree	`WORKTREE_EXISTS`	No
Branch name collision	`BRANCH_EXISTS`	No (use `--branch` flag to override)
`base_ref` not found	`BASE_REF_NOT_FOUND`	No
Disk full during worktree add	`DISK_FULL`	No
Any other git error	`GIT_ERROR`	No

---

8. Context Bundles

```
solo task context T-142 [--max-tokens N] --json
```

8.1 Bundle Structure

  }
}
```

8.2 Token Estimation and Truncation Priority

Token count estimated at ~0.75 tokens per whitespace-separated word.

If the output exceeds `--max-tokens`, fields are truncated from the **bottom of this list upwards** (lower number = higher priority = kept last):

1. `meta` + `system_directives` — **never truncated**
2. `task` core fields: `id`, `title`, `description`, `status`, `type`, `priority`
3. `reservation` + `worktree`

4. `latest_handoff`
5. `dependencies`
6. `task` extended fields: `acceptance_criteria`, `definition_of_done`, `affected_files`
7. `recent_sessions` — truncate oldest first
8. `error_history`
9. `duplicate_candidates` — truncated first

8.3 Input Sanitization

Applied to **all** fields with `trust_level: "untrusted"` before serialization:

Rule	Go Implementation
Null byte removal	`strings.ReplaceAll(s, "\x00", "")`
ANSI escape removal	`regexp.MustCompile("\x1b\\[[0-9;]*[a-zA-Z]").ReplaceAllString(s, "")`
Unicode normalization	`golang.org/x/text/unicode/norm` NFC normalization
JSON string escaping	Handled automatically by `encoding/json` marshaler

8.4 Duplicate Candidate Detection

When assembling a context bundle, run an FTS5 query against the task title and description to find potentially duplicate tasks:

```
SELECT t.id, t.title, t.status, bm25(tasks_fts) as rank
FROM tasks_fts
JOIN tasks t ON tasks_fts.id = t.id
WHERE tasks_fts MATCH ?
  AND t.id != ?
ORDER BY rank
LIMIT 5;
```

Include results in `duplicate_candidates`. The consuming agent can decide whether to check for prior work before proceeding.

---

9. Complete CLI Reference with JSON Contracts

CRITICAL IMPLEMENTATION NOTE ON JSON ARRAYS: SQLite columns storing JSON arrays (labels, affected_files, commits, etc.) are returned by Go's `database/sql` as raw strings. The implementation **must** explicitly `json.Unmarshal` these into native Go slices/structs before inserting them into the CLI response struct. Failure to do so produces double-encoded JSON strings (e.g., `"labels": "[\"bug\"]"`) which breaks agent parsers.

9.1 Initialization

```
solo init [--machine-id NAME] --json
```

```
{
  "initialized": true,
  "database": "/home/john/myrepo/.solo/solo.db",
  "machine_id": "laptop-john",
  "schema_version": 1
}
```

Errors: `ALREADY_INITIALIZED` if `.solo/solo.db` already exists.

9.2 Task Commands

```
solo task create --title "..." [--type T] [--priority N] [--description "..."] [--acceptance-criteria "..."] [--definition-of-done "..."] [--parent T-100] [--labels bug,backend] [--affected-files src/sync.go] [--deps T-140,T-141] --json
```

```
{
  "task": {
    "id": "T-142",
    "title": "Fix retry logic",
    "type": "bug",
    "status": "open",
    "priority": 3,
    "version": 1,
    "created_at": "2026-03-07T15:00:00.000Z"
  }
}
```

```
solo task list [--status ready] [--label bug] [--available] [--limit 20] [--offset
```

0] --json

`--available` = `status = 'ready'` AND no active reservation.

```
{
  "tasks": [
    {
      "id": "T-142",
      "title": "Fix retry logic",
      "type": "bug",
      "status": "ready",
      "priority": 3,
      "labels": ["backend"],
      "version": 2,
      "updated_at": "2026-03-07T15:00:00.000Z"
    }
  ],
  "total": 1,
  "limit": 20,
  "offset": 0
}
```

---

solo task show T-142 --json

Returns the full task object including dependencies, active reservation (if any), and session count.

```
{
  "task": {
    "id": "T-142",
    "title": "Fix retry logic",
    "description": "...",
    "type": "bug",
    "status": "in_progress",
    "priority": 3,
    "acceptance_criteria": "...",
    "definition_of_done": "...",
    "affected_files": ["src/sync.go"],
    "labels": ["backend"],
    "parent_task": null,
    "version": 4,
    "created_at": "...",
    "updated_at": "..."
  },
```

```
  "dependencies": [],
  "active_reservation": {
    "id": "r-uuid",
    "worker_id": "claude-code",
    "expires_at": "..."
  },
  "session_count": 2
}
```

`solo task update T-142 --status triaged --version 4 --json`

Enforces OCC version check and the Strict Lock Rule (§5.3).

Errors: `TASK_LOCKED`, `VERSION_CONFLICT`, `INVALID_TRANSITION`, `TASK_NOT_FOUND`.

`solo task ready T-142 --version N --json` — Manually force task to `ready`. Requires version.

`solo task deps T-142 --json` — Show dependency tree with completion status.

`solo search "retry 503" [--status ready] [--limit 10] --json`

```
{
  "results": [
    {
      "task_id": "T-142",
      "title": "Fix HTTP 503 retry logic",
      "status": "ready",
      "fts5_rank": -3.21,
      "snippet": "...retry logic in sync.go doesn't handle 503..."
    }
  ],
  "total": 1
}
```

9.3 Session Commands

`solo session start T-142 --worker claude-code [--ttl 7200] [--pid 12345] --json`

Atomically reserves the task, creates a session, allocates a worktree, and returns the full context bundle.

`--pid` defaults to the current process PID (`os.Getpid()`). Agents may override if they know the long-running process PID.

```
{
  "session_id": "s-uuid",
  "reservation_id": "r-uuid",
  "worktree_path": ".solo/worktrees/T-142",
  "branch": "solo/laptop-john/T-142",
  "expires_at": "2026-03-07T16:00:00.000Z",
  "context": { /* full context bundle per §8.1 */ }
}
```

Errors: `TASK_LOCKED`, `TASK_NOT_READY`, `TASK_NOT_FOUND`, `REPO_EMPTY`, `WORKTREE_LIMIT_EXCEEDED`, `WORKTREE_ERROR`, `VERSION_CONFLICT`.

`solo session end T-142 --result completed [--notes "..."] [--commits abc1234,def5678] [--status done] --json`

```
{
  "session_id": "s-uuid",
  "task_id": "T-142",
  "result": "completed",
  "task_status": "in_review",
  "ended_at": "2026-03-07T15:45:00.000Z"
}
```

Valid `--result` values: `completed`, `failed`, `interrupted`, `abandoned`.

`solo session list [--task T-142] [--worker claude-code] [--active] --json`

```
{
  "sessions": [
    {
      "id": "s-uuid",
      "task_id": "T-142",
      "worker_id": "claude-code",
      "started_at": "...",
      "ended_at": null,
      "result": null
    }
  ]
```

```
}
```

`solo reservation renew T-142 --json`

Extends the reservation TTL. Only the current reservation holder can renew.

```
{
  "reservation": {
    "id": "r-uuid",
    "task_id": "T-142",
    "new_expires_at": "2026-03-07T18:00:00.000Z",
    "remaining_sec": 7200
  }
}
```

9.4 Handoff Commands

`solo handoff create T-142 --summary "..." [--remaining-work "..."] [--to aider] [--files src/sync.go] --json`

Atomically ends the current session, releases the reservation, creates the handoff record, and transitions the task to `ready`.

```
{
  "handoff_id": "h-uuid",
  "task_id": "T-142",
  "from_worker": "claude-code",
  "to_worker": "aider",
  "task_status": "ready",
  "session_ended": true,
  "reservation_released": true
}
```

Errors: `NO_ACTIVE_SESSION`, `VERSION_CONFLICT`.

`solo handoff list [--task T-142] [--status pending] --json`

`solo handoff show H-uuid --json`

9.5 Worktree Commands

solo worktree list --json

```
{
  "worktrees": [
    {
      "path": ".solo/worktrees/T-142",
      "task_id": "T-142",
      "branch": "solo/laptop-john/T-142",
      "status": "active",
      "disk_usage_mb": 45,
      "created_at": "..."
    }
  ],
  "total": 2,
  "max": 5
}
```

solo worktree inspect T-142 --json

```
{
  "path": ".solo/worktrees/T-142",
  "task_id": "T-142",
  "branch": "solo/laptop-john/T-142",
  "status": "active",
  "git_status": "clean",
  "uncommitted_files": [],
  "ahead_commits": 2,
  "behind_commits": 0,
  "disk_usage_mb": 45
}
```

solo worktree cleanup [T-142] [--force] --json

9.6 Recovery Commands

solo task recover T-142 --version N --json

```
{
  "recovered": true,
  "task_id": "T-142",
  "previous_status": "in_progress",
  "recovered_to": "ready",
```

```
  "session_ended": "s-uuid",
  "reservation_released": "r-uuid",
  "worktree_state": "clean",
  "recovery_record_id": 7
}
```

solo recover --all --json

```
{
  "scanned": 5,
  "recovered": 2,
  "records": [
    {
      "task_id": "T-139",
      "session_id": "s-uuid",
      "dead_pid": 49231,
      "reason": "crash_detected"
    }
  ]
}
```

9.7 Health

solo health --json

```
{
  "database": {
    "path": ".solo/solo.db",
    "size_bytes": 102400,
    "integrity": "ok"
  },
  "schema_version": 1,
  "machine_id": "laptop-john",
  "tasks": {
    "open": 5, "triaged": 2, "ready": 3, "in_progress": 2,
    "in_review": 1, "blocked": 1, "done": 42, "cancelled": 0
  },
  "active_reservations": 2,
  "active_sessions": 2,
  "zombie_sessions": 0,
  "expired_reservations": 0,
  "worktrees": {
    "active": 2, "cleanup_pending": 0, "max": 5, "disk_usage_mb": 340
  },
```

```
  "pending_handoffs": 1,
  "issues": []
}
```

---

10. Error Taxonomy

Every error returns this structure when `--json` is active:

```
{
  "error": {
    "code": "ERROR_CODE",
    "message": "Human-readable description.",
    "retryable": true,
    "retry_hint": "What to do to retry successfully."
  }
}
```

Exit code: `0` on success, `1` on all errors.

Code	Trigger	Retryable	Hint
`NOT_A_REPO`	No `.git` found walking up from CWD	No	Run inside a git repo
`TASK_NOT_FOUND`	Invalid task ID	No	Check ID with `solo task list`
`TASK_NOT_READY`	Task status is not `ready`	No	Check status with `solo task show`
`TASK_LOCKED`	Active reservation exists on task	No	Wait for agent to finish, or use `solo task recover`
`NO_ACTIVE_SESSION`	Session end/handoff with no active session	No	Check `solo session list --task T-N`
`HANDOFF_LOCKED`	Pending handoff is locked to specific worker	No	Pick a different task
	OCC version		Re-read current

`VERSION_CONFLICT`	mismatch	Yes	version, retry
`INVALID_TRANSITION`	Illegal status change	No	Check §5.1 for valid transitions
`CIRCULAR_DEPENDENCY`	Dependency would create a cycle	No	Review dependency graph
`REPO_EMPTY`	Repo has 0 commits	No	Make an initial commit before using worktrees
`WORKTREE_DIRTY`	Uncommitted changes block cleanup	No	Commit/stash, or use `--force`
`WORKTREE_EXISTS`	Worktree path already exists	No	Run `solo worktree cleanup`
`WORKTREE_LIMIT_EXCEEDED`	Active worktrees >= max_worktrees	No	Clean up with `solo worktree cleanup`
`GIT_INDEX_LOCKED`	`.git/index.lock` exists	Yes	Auto-retried 3×, then surfaces as error
`GIT_ERROR`	Unclassified git failure	No	Check git output in message
`BASE_REF_NOT_FOUND`	Configured base_ref doesn't exist	No	Run `git fetch` or update config
`ALREADY_INITIALIZED`	`solo init` on already-initialized repo	No	—
`SQLITE_BUSY`	DB locked beyond busy_timeout	Yes	Retry after brief delay
`ALREADY_INITIALIZED`	`solo init` run twice	No	Already set up

---

11. Implementation Invariants (Hard Guardrails)

If an AI coding agent is reading this, **strictly adhere to these invariants**. Do not skip any of them.

1. **Every write operation MUST be inside `BEGIN IMMEDIATE ... COMMIT`.** No exceptions. No bare `INSERT`, `UPDATE`, or `DELETE` outside a transaction.
2. **Every SQLite JSON field MUST be `json.Unmarshal`-ed in Go before JSON re-serialization.** Never pass raw SQLite string values into a JSON response struct for array/object fields.
3. **Tasks with active reservations CANNOT be mutated via `solo task update`.** The Strict Lock Rule (§5.3) must be enforced on every write path.
4. **The Lazy Zombie scan MUST use `PRAGMA busy_timeout = 0`.** This prevents latency storms where all concurrent CLI invocations block on each other's zombie scans.
5. **OCC version fields MUST be validated on every state transition**, including `solo task recover`. No unconditional `UPDATE tasks SET status = ?`.
6. **`os.Stat` MUST be used to find `.git`**, not `exec.Command("git", "rev-parse", "--git-dir")`. The `os.Stat` approach works correctly from inside a worktree; the git command approach does not.
7. **`git rev-parse HEAD` MUST be checked before `git worktree add`** to prevent crashes on empty repositories.
8. **All timestamps MUST be ISO 8601 with milliseconds and UTC suffix.** Format: `2026-03-07T15:00:00.000Z`. Use SQLite's `strftime('%Y-%m-%dT%H:%M:%fZ', 'now')`.
9. **Solo never spawns agents.** Solo is a ledger. It records what agents do. It does not run, schedule, or manage agents.
10. **Solo never deletes worktrees with uncommitted changes without `--force`.**

---

12. Configuration Reference

All config values stored in the `config` table. Set by `solo init`, readable by all commands.

Key	Default	Description
`machine_id`	hostname	Identifies this machine in branch names and records
`default_ttl_sec`	`3600`	Default reservation TTL (1 hour)

`max_ttl_sec`	`86400`	Maximum allowed TTL (24 hours)
`max_worktrees`	`5`	Maximum simultaneous active worktrees
`base_ref`	`origin/main`	Git ref used as base for new worktree branches
`worktree_dir`	`.solo/worktrees`	Directory where worktrees are created
`session_ttl_sec`	`14400`	Session TTL for zombie scan expiry (4 hours)
`max_tokens`	`8000`	Default token budget for context bundles

---

13. Development Phases

Implement Solo in this order. Each phase must be complete and tested before starting the next.

Phase 1: Foundation

`solo init`, full schema creation, PRAGMAs on every connection, schema migrations framework, `solo health`.

Test: Concurrent writes don't corrupt DB. `PRAGMA integrity_check` passes. FTS5 triggers fire correctly.

Phase 2: Task CRUD + Lifecycle

Task create/list/show/update, ID generation, OCC, status transitions, dependencies, labels, FTS5 search, audit events.

Test: 100 tasks created. All invalid transitions rejected. Concurrent OCC conflicts return `VERSION_CONFLICT`. FTS5 search returns correct results. Circular dependency insertion fails.

Phase 3: Sessions + Reservations

`solo session start` (full atomic sequence), `solo session end`, `solo reservation renew/list`, lazy zombie scan, PID-based crash detection.

Test: Concurrent double-reserve: exactly one wins, all others get `TASK_LOCKED`. PID kill → zombie detected on next CLI invocation. Reservation expiry → task recovered to `ready`.

Phase 4: Worktrees

Worktree allocation in session start, worktree registry, `solo worktree list/inspect/cleanup`, all git error classifications (§7.4), disk budget enforcement.

Test: Max worktree limit enforced. Dirty worktree cleanup refused without `--force`. `GIT_INDEX_LOCKED` retried 3× before surfacing. Branch naming format verified.

Phase 5: Handoffs

Atomic handoff create, `solo handoff list/show`, handoff data in context bundle.

Test: Handoff → session ended + reservation released + task ready, all atomically. Next session sees handoff in context bundle. `to_worker` filter works.

Phase 6: Context Bundles

`solo task context`, token estimation, truncation priority, trust level labeling, sanitization, duplicate candidate detection.

Test: Truncation fires correctly at low token budget. ANSI sequences and null bytes stripped from untrusted fields. All untrusted fields carry `trust_level` marker. Duplicate candidates populated from FTS5.

Phase 7: Recovery + Polish

`solo task recover`, `solo recover --all`, recovery records, worktree state capture in recovery, `solo health` enhancements.

Test: PID kill → `solo recover --all` → full recovery. Already-recovered session is a no-op. Recovery record persisted and retrievable.

Phase 8: Integration Testing

End-to-end workflows: single agent completes task, handoff chain A→B→A, crash during active session, 5 agents competing for 1 task, 1000-task stress test.

---

14. Assumptions

- Git 2.20+ (worktree support required)
- Go 1.21+
- SQLite 3.35+ (for `RETURNING`, `strftime` with milliseconds, FTS5)
- Single machine, single user, multiple concurrent agent CLI processes

- Agents call Solo. Solo never spawns agents.
- `.solo/` directory should be added to `.gitignore`

---

15. Invariants Checklist

Before marking any phase complete, verify all 10 invariants (§11) are enforced end-to-end.

1. ☐ Every write in `BEGIN IMMEDIATE ... COMMIT`
2. ☐ All JSON array/object fields unmarshaled before serialization
3. ☐ Strict Lock Rule enforced on `solo task update`
4. ☐ Zombie scan uses `busy_timeout = 0`
5. ☐ OCC version check on every state transition
6. ☐ `os.Stat` used for `.git` discovery
7. ☐ `git rev-parse HEAD` checked before `git worktree add`
8. ☐ Timestamps in ISO 8601 with milliseconds and UTC
9. ☐ Solo never spawns agents
10. ☐ Worktrees with uncommitted changes protected without `--force`
